- This time:
  - Padded RSA Encryption
  - Digital Signatures Definitions (12.2-12.3)
  - RSA Signatures (12.4)

# Padded RSA

## *CONSTRUCTION 11.29*

Let GenRSA be as before, and let  $\ell$  be a function with  $\ell(n) \leq 2n - 4$  for all  $n$ . Define a public-key encryption scheme as follows:

- Gen: on input  $1^n$ , run GenRSA( $1^n$ ) to obtain  $(N, e, d)$ . Output the public key  $pk = \langle N, e \rangle$ , and the private key  $sk = \langle N, d \rangle$ .
- Enc: on input a public key  $pk = \langle N, e \rangle$  and a message  $m \in \{0, 1\}^{\|N\| - \ell(n) - 2}$ , choose a random string  $r \leftarrow \{0, 1\}^{\ell(n)}$  and interpret  $\hat{m} := 1\|r\|m$  as an element of  $\mathbb{Z}_N^*$ . Output the ciphertext

$$c := [\hat{m}^e \bmod N].$$

- Dec: on input a private key  $sk = \langle N, d \rangle$  and a ciphertext  $c \in \mathbb{Z}_N^*$ , compute

$$\hat{m} := [c^d \bmod N],$$

and output the  $\|N\| - \ell(n) - 2$  least-significant bits of  $\hat{m}$ .

The padded RSA encryption scheme.

# Digital Signatures Definition

A digital signature scheme consists of three ppt algorithms  $(Gen, Sign, Vrfy)$  such that:

1. The key-generation algorithm  $Gen$  takes as input a security parameter  $1^n$  and outputs a pair of keys  $(pk, sk)$ . We assume that  $pk, sk$  each have length at least  $n$ , and that  $n$  can be determined from  $pk$  or  $sk$ .
2. The signing algorithm  $Sign$  takes as input a private key  $sk$  and a message  $m$  from some message space (that may depend on  $pk$ ). It outputs a signature  $\sigma$ , and we write this as  $\sigma \leftarrow Sign_{sk}(m)$ .
3. The deterministic verification algorithm  $Vrfy$  takes as input a public key  $pk$ , a message  $m$ , and a signature  $\sigma$ . It outputs a bit  $b$ , with  $b = 1$  meaning valid and  $b = 0$  meaning invalid. We write this as  $b := Vrfy_{pk}(m, \sigma)$ .

Correctness: It is required that except with negligible probability over  $(pk, sk)$  output by  $Gen(1^n)$ , it holds that  $Vrfy_{pk}(m, Sign_{sk}(m)) = 1$  for every message  $m$ .

# Digital Signatures Definition: Security

Experiment  $SigForge_{A,\Pi}(n)$ :

1.  $Gen(1^n)$  is run to obtain keys  $(pk, sk)$ .
2. Adversary  $A$  is given  $pk$  and access to an oracle  $Sign_{sk}(\cdot)$ . The adversary then outputs  $(m, \sigma)$ . Let  $Q$  denote the set of all queries that  $A$  asked to its oracle.
3.  $A$  succeeds if and only if
  1.  $Vrfy_{pk}(m, \sigma) = 1$
  2.  $m \notin Q$ .

In this case the output of the experiment is defined to be 1.

Definition: A signature scheme  $\Pi = (Gen, Sign, Vrfy)$  is existentially unforgeable under an adaptive chosen-message attack, if for all ppt adversaries  $A$ , there is a negligible function  $neg$  such that:

$$\Pr[SigForge_{A,\Pi}(n) = 1] \leq neg(n).$$

# RSA Signatures

## *CONSTRUCTION 12.5*

Let GenRSA be as in the text. Define a signature scheme as follows:

- Gen: on input  $1^n$  run GenRSA( $1^n$ ) to obtain  $(N, e, d)$ . The public key is  $\langle N, e \rangle$  and the private key is  $\langle N, d \rangle$ .
- Sign: on input a private key  $sk = \langle N, d \rangle$  and a message  $m \in \mathbb{Z}_N^*$ , compute the signature

$$\sigma := [m^d \bmod N].$$

- Vrfy: on input a public key  $pk = \langle N, e \rangle$ , a message  $m \in \mathbb{Z}_N^*$ , and a signature  $\sigma \in \mathbb{Z}_N^*$ , output 1 if and only if

$$m \stackrel{?}{=} [\sigma^e \bmod N].$$

The plain RSA signature scheme.

# Attacks

No message attack:

Choose  $s \in Z_N^*$ , compute  $s^e$ .

Output  $(m = s^e, \sigma = s)$  as the forgery.

# Attacks

Forging a signature on an arbitrary message:

To forge a signature on message  $m$ , choose arbitrary  $m_1, m_2 \neq 1$  such that  $m = m_1 \cdot m_2$ .

Query oracle for  $(m_1, \sigma_1), (m_2, \sigma_2)$ .

Output  $(m, \sigma)$ , where  $\sigma = \sigma_1 \cdot \sigma_2$ .

# RSA-FDH

## *CONSTRUCTION 12.6*

Let  $\text{GenRSA}$  be as in the previous sections, and construct a signature scheme as follows:

- **Gen**: on input  $1^n$ , run  $\text{GenRSA}(1^n)$  to compute  $(N, e, d)$ . The public key is  $\langle N, e \rangle$  and the private key is  $\langle N, d \rangle$ .

As part of key generation, a function  $H : \{0, 1\}^* \rightarrow \mathbb{Z}_N^*$  is specified, but we leave this implicit.

- **Sign**: on input a private key  $\langle N, d \rangle$  and a message  $m \in \{0, 1\}^*$ , compute

$$\sigma := [H(m)^d \bmod N].$$

- **Vrfy**: on input a public key  $\langle N, e \rangle$ , a message  $m$ , and a signature  $\sigma$ , output 1 if and only if  $\sigma^e \stackrel{?}{=} H(m) \bmod N$ .

The RSA-FDH signature scheme.

# Random Oracles

- Assume certain hash functions behave exactly like a random oracle.
- The “oracle” is a box that takes a binary string as input and returns a binary string as output.
- The internal workings of the box are unknown.
- All parties (honest parties and adversary) have access to the box.
- The box is consistent.
- Oracle implements a random function by choosing values of  $H(x)$  “on the fly.”

# Principles of RO Model

1. If  $x$  has not been queried to  $H$ , then the value of  $H(x)$  is uniform.
2. If  $A$  queries  $x$  to  $H$ , the reduction can see this query and learn  $x$ .
3. The reduction can set the value of  $H(x)$  to a value of its choice, as long as this value is correctly distributed, i.e., uniform.

# Security of RSA-FDH

Theorem: If the RSA problem is hard relative to  $GenRSA$  and  $H$  is modeled as a random oracle, then the construction above is secure.

# PKCS #1 v2.1

- Uses an instantiation of RSA-FDH for signing.
- SHA-1 should not be used “off-the-shelf” as an instantiation of  $H$  because output length is too small and so practical short-message attacks apply.
- In PKCS #1 v2.1,  $H$  is constructed via repeated application of an underlying cryptographic hash function.
