

Lattice-Based Crypto

Lecture 27

Traditional Crypto Assumptions

- Factoring: Given $N = pq$, find p, q
 - RSA Given $N = pq, e, x^e \bmod N$, find x .
- Discrete Log: Given $g^x \bmod p$, find x .
 - Diffie-Hellman Assumptions (g^x, g^y, g^{xy}) ,
 (g^x, g^y, g^z)

Are They Secure?

- Algorithmic Advances:
 - Factoring: Best algorithm time $2^{\tilde{O}(n^{\frac{1}{3}})}$ to factor n -bit number.
 - Discrete log: Best algorithm $2^{\tilde{O}(n^{\frac{1}{3}})}$ for groups Z_p^* , where p is n bits.
 - [Adrian et al. 2015] With preprocessing could possibly be feasible for nation-states and $n = 1024$.
 - Quasipolynomial time algorithms for small characteristic fields. Not known to apply in practice.
- Quantum Computers:
 - Shor's algorithm solves both factoring and discrete log in quantum polynomial time ($\tilde{O}(n^2)$).

Are They Secure?

“For those partners and vendors that have not yet made the transition to Suite B algorithms (ECC), we recommend not making a significant expenditure to do so at this point but instead to **prepare for the upcoming quantum resistant algorithm transition**.... Unfortunately, the growth of elliptic curve use has bumped up against the fact of continued progress in the research on quantum computing, necessitating a re-evaluation of our cryptographic strategy. ”—NSA Statement, August 2015

NIST Kicks Off Effort to Defend Encrypted Data from Quantum Computer Threat

Post-Quantum Approach

- New set of assumptions based on finding short vectors in lattices.
- Believed to be hard for quantum computers.
- Evidence of hardness “worst case to average case reduction”.
- Versatile: Can essentially construct all cryptosystems out of these assumptions.

The LWE Problem (Search)

Secret n -dimension vector s
with entries chosen at random

Operations are mod p .

$$A \times s + e = As+e$$

Public $m \times n$ matrix A , with
entries chosen at random
over Z_p

m -dimension error
vector e , with entries
sampled from χ .

**Distribution χ depends
on dimension of A and
the modulus.**

Problem: Given, A , $As+e$, find s .

The LWE Problem Decision

Secret n -dimension vector s
with entries chosen at random

Operations are mod p .

A diagram illustrating the LWE equation. On the left is a large red rectangle labeled 'A'. To its right is a multiplication symbol '×', followed by a blue vertical rectangle labeled 's'. To the right of 's' is a plus sign '+', followed by a green horizontal rectangle labeled 'e'. To the right of 'e' is an equals sign '=', followed by a purple horizontal rectangle labeled 'As+e'.

Public $m \times n$ matrix A , with
entries chosen at random
over Z_p

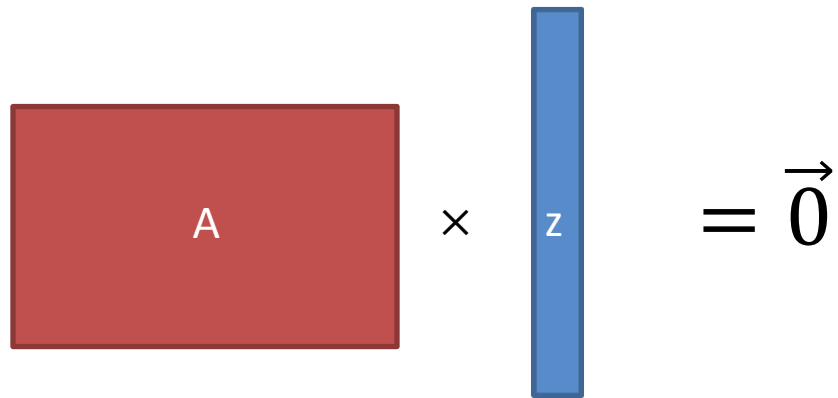

m -dimension error
vector e , with entries
sampled from χ

\approx

An orange horizontal rectangle labeled 'u'.

m uniform random
elements from Z_p

The SIS Problem

$$A \times z = \vec{0}$$

Public $n \times m$ matrix A , with entries chosen at random over Z_p

Problem: Given A , find $z \in \{0,1\}^m$

Lattices

An n -dimensional lattice L is an additive discrete subgroup of R^n . A basis $\mathbf{B} \in R^{n \times n}$ defines a lattice $L(\mathbf{B})$ in the following way:

$$L(\mathbf{B}) = \{\mathbf{v} \in R^n \text{ s.t. } \mathbf{v} = \mathbf{B}\mathbf{z} \text{ for some } \mathbf{z} \in Z^n\}.$$

“integer linear combinations of the basis vectors”

i -th successive minima $\lambda_i(L(\mathbf{B}))$: The smallest radius r such that there are i linearly independent vectors $\{v_1, \dots, v_i\}$ of length at most r .

Hard Lattice Problems

- Are all parameterized by “approximation factor” $\gamma > 1$.
- **Shortest Vector Problem (SVP)**: Given a basis B , find a non-zero vector $v \in L(B)$ whose length is at most $\gamma \cdot \lambda_1(L(B))$.
- **Shortest Independent Vector Problem (SIVP)**: Given a basis B , find a linearly independent set $\{v_1, \dots, v_n\}$ such that all vectors have length at most $\gamma \cdot \lambda_n(L(B))$.
- **Gap Shortest vector problem (GapSVP)**: Given a basis B , and a radius $r > 0$
 - Return YES if $\lambda_1(L(B)) \leq r$
 - Return NO if $\lambda_1(L(B)) > \gamma \cdot r$.

Relation to LWE, SIS

- Worst-Case to Average-Case Reduction: Breaking the cryptosystem on average is as hard as breaking the hardest instance of the underlying lattice problem.
- SIS:
 - Worst-Case to Average-Case Reduction from SIVP.
- LWE:
 - Worst-Case to Average-Case **Quantum** Reduction from SIVP.
 - Worst-Case to Average-Case **Classical** Reductions from GapSVP.

Lattice-Based Encryption

Regev's Cryptosystem

Public
Key:

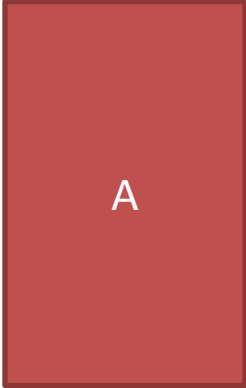

$$u = As + e$$

Secret
Key:

Regev's Cryptosystem

Encryption of $m \in \{0,1\}$

(1)  × 

$r \in \{0,1\}^m$ chosen at random.

(2)  ·  + $m \cdot \left\lfloor \frac{p}{2} \right\rfloor$

Regev's Cryptosystem

Decryption

$$\boxed{r} \cdot \boxed{u=As+e}$$

$$+ m \cdot \left\lfloor \frac{p}{2} \right\rfloor$$

—

$$\left[\boxed{r} \times \boxed{A} \right] \cdot \boxed{s}$$

Regev's Cryptosystem

Decryption

—

$$r \cdot u = As + e$$

$$+ m \cdot \left\lfloor \frac{p}{2} \right\rfloor$$

$$r \cdot \left[A \times s \right]$$

Regev's Cryptosystem

Decryption

$$\boxed{r} \cdot \boxed{u=As+e} + m \cdot \left\lfloor \frac{p}{2} \right\rfloor$$

$$\boxed{r} \cdot \boxed{As}$$

$$\boxed{r} \cdot \boxed{e} + m \cdot \left\lfloor \frac{p}{2} \right\rfloor$$

Regev's Cryptosystem

Decryption

$$\boxed{r} \cdot \boxed{u=As+e} \quad + m \cdot \left\lfloor \frac{p}{2} \right\rfloor$$

$$\boxed{r} \cdot \left[\boxed{As} \right]$$

≈ 0

$$+ m \cdot \left\lfloor \frac{p}{2} \right\rfloor$$

Thank You!
