

# Introduction to Cryptology

## Lecture 6

# Announcements

- HW2 due Thursday, 2/15
- Readings/Quizzes on Canvas due today (11:59pm)
- Pick up graded HW1 after class

# Agenda

- Last time:
  - One time pad (OTP) (K/L 2.2)
  - Limitations of perfect secrecy (K/L 2.3)
- This time:
  - Shannon's Theorem and examples (K/L 2.4)
  - The Computational Approach (K/L 3.1)
  - Defining computationally secure SKE (K/L 3.2)

# Shannon's Theorem

Let  $(Gen, Enc, Dec)$  be an encryption scheme with message space  $\mathbf{M}$ , for which  $|\mathbf{M}| = |\mathbf{K}| = |\mathbf{C}|$ . The scheme is perfectly secret if and only if:

1. Every key  $k \in \mathbf{K}$  is chosen with equal probability  $1/|\mathbf{K}|$  by algorithm  $Gen$ .
2. For every  $m \in \mathbf{M}$  and every  $c \in \mathbf{C}$ , there exists a unique key  $k \in \mathbf{K}$  such that  $Enc_k(m)$  outputs  $c$ .

\*\*Theorem only applies when  $|\mathbf{M}| = |\mathbf{K}| = |\mathbf{C}|$ .

# Some Examples

- Is the following scheme perfectly secret?
- Message space  $M = \{0, 1, \dots, n - 1\}$ . Key space  $K = \{0, 1, \dots, n - 1\}$ .
- $\text{Gen}()$  chooses a key  $k$  at random from  $K$ .
- $\text{Enc}_k(m)$  returns  $m + k$ .
- $\text{Dec}_k(c)$  returns  $c - k$ .

# Some Examples

- Is the following scheme perfectly secret?
- Message space  $M = \{0, 1, \dots, n - 1\}$ . Key space  $K = \{0, 1, \dots, n - 1\}$ .
- $\text{Gen}()$  chooses a key  $k$  at random from  $K$ .
- $\text{Enc}_k(m)$  returns  $m + k \bmod n$ .
- $\text{Dec}_k(c)$  returns  $c - k \bmod n$ .

# The Computational Approach

Two main relaxations:

1. Security is only guaranteed against efficient adversaries that run for some feasible amount of time.
2. Adversaries can potentially succeed with some very small probability.

# Security Parameter

- Integer valued security parameter denoted by  $n$  that parameterizes both the cryptographic schemes as well as all involved parties.
- When honest parties initialize a scheme, they choose some value  $n$  for the security parameter.
- Can think of security parameter as corresponding to the length of the key.
- Security parameter is assumed to be known to any adversary attacking the scheme.
- View run time of the adversary and its success probability as functions of the security parameter.

# Polynomial Time

- Efficient adversaries = Polynomial time adversaries
  - There is some polynomial  $p$  such that the adversary runs for time at most  $p(n)$  when the security parameter is  $n$ .
  - Honest parties also run in polynomial time.
  - The adversary may be much more powerful than the honest parties.

# Negligible

- Small probability of success = negligible probability
  - A function  $f$  is negligible if for every polynomial  $p$  and all sufficiently large values of  $n$  it holds that
$$f(n) < \frac{1}{p(n)}.$$
  - Intuition,  $f(n) < n^{-c}$  for every constant  $c$ , as  $n$  goes to infinity.

# Negligible

# Practical Implications of Computational Security

- For key size  $n$ , any adversary running in time  $2^{n/2}$  breaks the scheme with probability  $1/2^{n/2}$ .
- Meanwhile, *Gen*, *Enc*, *Dec* each take time  $n^2$ .
- If  $n = 128$  then:
  - *Gen*, *Enc*, *Dec* take time 16,384
  - Adversarial run time is  $2^{64} \approx 10^{18}$
- If  $n = 256$  then:
  - *Gen*, *Enc*, *Dec* quadruples--takes time 65,536
  - Adversary run time is multiplied by  $2^{64}$ . Becomes  $2^{128} \approx 10^{38}$

# Defining Computationally Secure Encryption

A **private-key encryption scheme** is a tuple of probabilistic polynomial-time algorithms  $(Gen, Enc, Dec)$  such that:

1. The **key-generation algorithm**  $Gen$  takes as input security parameter  $1^n$  and outputs a key  $k$  denoted  $k \leftarrow Gen(1^n)$ . We assume WLOG that  $|k| \geq n$ .
2. The encryption algorithm  $Enc$  takes as input a key  $k$  and a message  $m \in \{0,1\}^*$ , and outputs a ciphertext  $c$  denoted  $c \leftarrow Enc_k(m)$ .
3. The decryption algorithm  $Dec$  takes as input a key  $k$  and ciphertext  $c$  and outputs a message  $m$  denoted by  $m := Dec_k(c)$ .

Correctness: For every  $n$ , every key  $k \leftarrow Gen(1^n)$ , and every  $m \in \{0,1\}^*$ , it holds that  $Dec_k(Enc_k(m)) = m$ .

# Indistinguishability in the presence of an eavesdropper

Consider a private-key encryption scheme  $\Pi = (Gen, Enc, Dec)$ , any adversary  $A$ , and any value  $n$  for the security parameter.

The eavesdropping indistinguishability experiment  $PrivK^{eav}_{A,\Pi}(n)$ :

1. The adversary  $A$  is given input  $1^n$ , and outputs a pair of messages  $m_0, m_1$  of the same length.
2. A key  $k$  is generated by running  $Gen(1^n)$ , and a random bit  $b \leftarrow \{0,1\}$  is chosen. A challenge ciphertext  $c \leftarrow Enc_k(m_b)$  is computed and given to  $A$ .
3. Adversary  $A$  outputs a bit  $b'$ .
4. The output of the experiment is defined to be 1 if  $b' = b$ , and 0 otherwise. If  $PrivK^{eav}_{A,\Pi}(n) = 1$ , we say that  $A$  succeeded.

# Indistinguishability in the presence of an eavesdropper

Definition: A private key encryption scheme  $\Pi = (Gen, Enc, Dec)$  has **indistinguishable encryptions in the presence of an eavesdropper** if for all probabilistic polynomial-time adversaries  $A$  there exists a negligible function  $negl$  such that

$$\Pr \left[ PrivK^{eav}_{A, \Pi}(n) = 1 \right] \leq \frac{1}{2} + negl(n),$$

Where the prob. is taken over the random coins used by  $A$ , as well as the random coins used in the experiment.
